SCOPE ON THE SKIES

Getting to the Core of Climate Change

BY BOB RIDDLE

What image may come to mind when the word glacier is heard? Before answering that question, here is another one: glaciers are part of the Earth's "cryosphere"—no what is the cryosphere? The cryosphere includes any place on our planet's surface covered with water in the form of snow, ice on land or sea, and permafrost. As such, the cryosphere is part of the hydrosphere and could be thought of as the "frozen water" part of the Earth. The cryosphere plays a significant role in our planet's climate, and an understanding of how climate has changed in the past may provide information about what to expect in the future. Scientists that study the climate history of the cryosphere (paleoclimatology) study global ice in a variety of ways, including data and observations from Earth's orbit, flyovers with instrument-equipped airplanes, and a ground-based collection of observations and data (see Hunting for Ice on Hudson Bay in Resources).

NASA's Operation IceBridge is an airborne flyover of the ice at both the North and South Pole. A variety of instrument-documented changes in the gain or loss in the thickness and mass of ice on land and sea as well as glaciers. Data collected by IceBridge is added to data from previous and current NASA satellite missions, ICESat, ICESat-2, and the ESA's satellite missions CryoSat and CryoSat-2 (see Resources). All the airborne and satellite missions make some of the measurements using either radar or laser altimetry. As a side note, this is the technology that allowed us to map the surface of Venus, for example (see

Introduction

Biology, study of living things and their vital processes. The field deals with all the physicochemical aspects of life. The modern tendency toward cross-disciplinary research and the unification of scientific knowledge and investigation from different fields has resulted in significant overlap of the field of biology with other scientific disciplines. Modern principles of other fields—chemistry, medicine, and physics, for example—are integrated with those of biology in areas such as biochemistry, biomedicine, and biophysics.

Biology is subdivided into separate branches for convenience of study, though all the subdivisions are interrelated by basic principles. Thus, while it is custom to separate the study of **plants (botany)** from that of **animals (zoology)**, and the study of the structure of organisms (**morphology**) from that of function (**physiology**), all living things share in common certain biological phenomena—for example, various means of **reproduction, cell division**, and the transmission of genetic material.

Biology is often approached on the basis of levels that deal with fundamental units of life. At the level of **molecular biology**, for example, life is regarded as a manifestation of chemical and energy transformations that occur among the many chemical constituents that compose an organism. As a result of the development of increasingly powerful and precise laboratory instruments and techniques, it is possible to understand and define with high precision and accuracy not only the ultimate physicochemical organization (ultrastructure) of the molecules in living matter but also the way living matter reproduces at the molecular level. Especially crucial to those advances was the rise of **genomics** in the late 20th and early 21st centuries.

Cell biology is the study of cells—the fundamental units of structure and function in living organisms. **Cells** were first observed in the 17th century when the compound **microscope** was invented. Before that time, the
